

**Properties of Cosmic Helium Isotopes Measured by the Alpha
Magnetic Spectrometer**
- SUPPLEMENTAL MATERIAL -

(The AMS Collaboration)

For references see the main text.

Detector.— The layout and description of the AMS detector are presented in Ref. [14]. The key elements used in this measurement are the permanent magnet [15], the silicon tracker, the four planes of time of flight scintillation counters (TOF), and the ring imaging Čerenkov detector (RICH). AMS also contains a transition radiation detector (TRD), an electromagnetic calorimeter (ECAL), and an array of 16 anticoincidence counters.

The tracker measures the momentum divided by charge, or rigidity R , of charged cosmic rays deflected in the magnetic field. The tracker [16] has nine layers, the first (L1) at the top of the detector, the second (L2) above the magnet, six (L3 to L8) within the bore of the magnet, and the last (L9) above the ECAL. L2 to L8 constitute the inner tracker. The spatial resolution in each tracker layer is $6.5 \mu\text{m}$ in the bending direction for helium. The resolution of the rigidity measurement for helium is better than 10% below 20 GV and the maximum detectable rigidity (MDR) is 3.2 TV [8]. Each layer of the tracker provides an independent measurement of the charge magnitude Z . Overall, the inner tracker charge resolution is $\Delta Z = 0.07$ for $Z = 2$ nuclei.

Two planes of TOF counters [17] are located above and two planes are below the magnet. The TOF velocity ($\beta = v/c$) resolution has been measured to be $\Delta(1/\beta) = 0.02$ for $Z = 2$ particles. The pulse heights of the two upper TOF planes are combined to provide an independent measurement of the charge with an accuracy $\Delta Z = 0.08$ for $Z = 2$. The pulse heights from the two lower TOF planes are combined to provide an additional charge measurement with the same accuracy.

The RICH detector [18] measures the particle velocity and charge magnitude. It is located below the lower TOF and consists of two radiators, an expansion volume, and a photo-detection plane. The dielectric radiators induce the emission of a cone of Čerenkov photons when traversed by charged particles with a velocity greater than the velocity of light in the radiator. The central radiator is formed by sodium fluoride (RICH-NaF) of refractive index $n = 1.33$, it is surrounded by silica aerogel (RICH-Agl) of refractive index $n = 1.05$. This allows the detection of particles with velocities $\beta > 0.75$ for those which pass through the NaF radiator and $\beta > 0.953$ for those which pass through the Agl radiator. The expansion volume extends along z for 470 mm between the radiators and the photo-detection plane and it is surrounded by a high reflectivity mirror to increase detection efficiency. The photo-detection plane is an array of 10880 photosensors in multi-channel photomultiplier tubes with an effective spatial granularity of $8.5 \times 8.5 \text{ mm}^2$. For $Z = 2$ nuclei, the RICH velocity resolution $\Delta\beta$ is 25×10^{-4} for NaF and 7×10^{-4} for Agl. The RICH independently measures the nuclei charge by counting the number of Čerenkov photons with an accuracy for $Z = 2$ of $\Delta Z = 0.6$ for NaF and $\Delta Z = 0.3$ for Agl.

Helium nuclei traversing AMS are triggered as described in Ref. [8], with measured efficiencies $> 94\%$.

Monte Carlo (MC) simulated events were produced using a dedicated program developed by the collaboration based on the GEANT4 10.3 package [19]. The program simulates electromagnetic and hadronic interactions of particles in the material of the AMS and generates detector responses. The INCL++ package [20] was used to model helium-nuclear inelastic interactions below 5 GeV/n and the DPMJET-II.5 package [21] was used at higher energies. The helium-nuclear elastic and quasi-elastic scattering were modelled using the measurements from Ref. [8]. The helium-nuclear interactions with the materials in the AMS have been corrected accordingly to the results in Ref. [8]. The interaction cross sections of ${}^3\text{He}$ on AMS materials have been accounted following the measurements in Ref. [22].

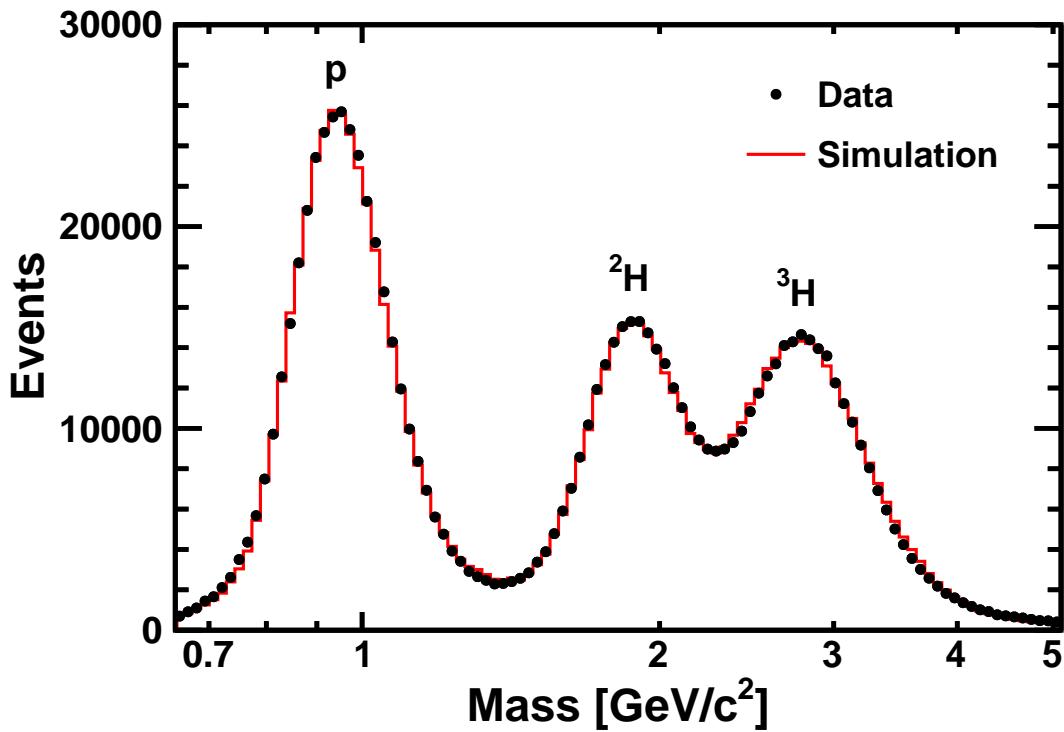

FIG. S1. Mass distribution for events interacting between tracker L1 and L2 with $0.9721 < \beta < 0.9954$. The events were selected by requiring a measured charge of $Z = 2$ in tracker L1, and charge $Z = 1$ in the inner tracker (L2 to L8). The rigidity R is measured with the inner tracker. The velocity β is measured with RICH-Agl. The MC simulation (red histogram) is normalized to the total number of events in the data (black points). Peaks corresponding to proton, deuterium (^2H), and tritium (^3H) nuclei produced from interactions of He with AMS materials are clearly visible. The data and the MC simulation agree well.

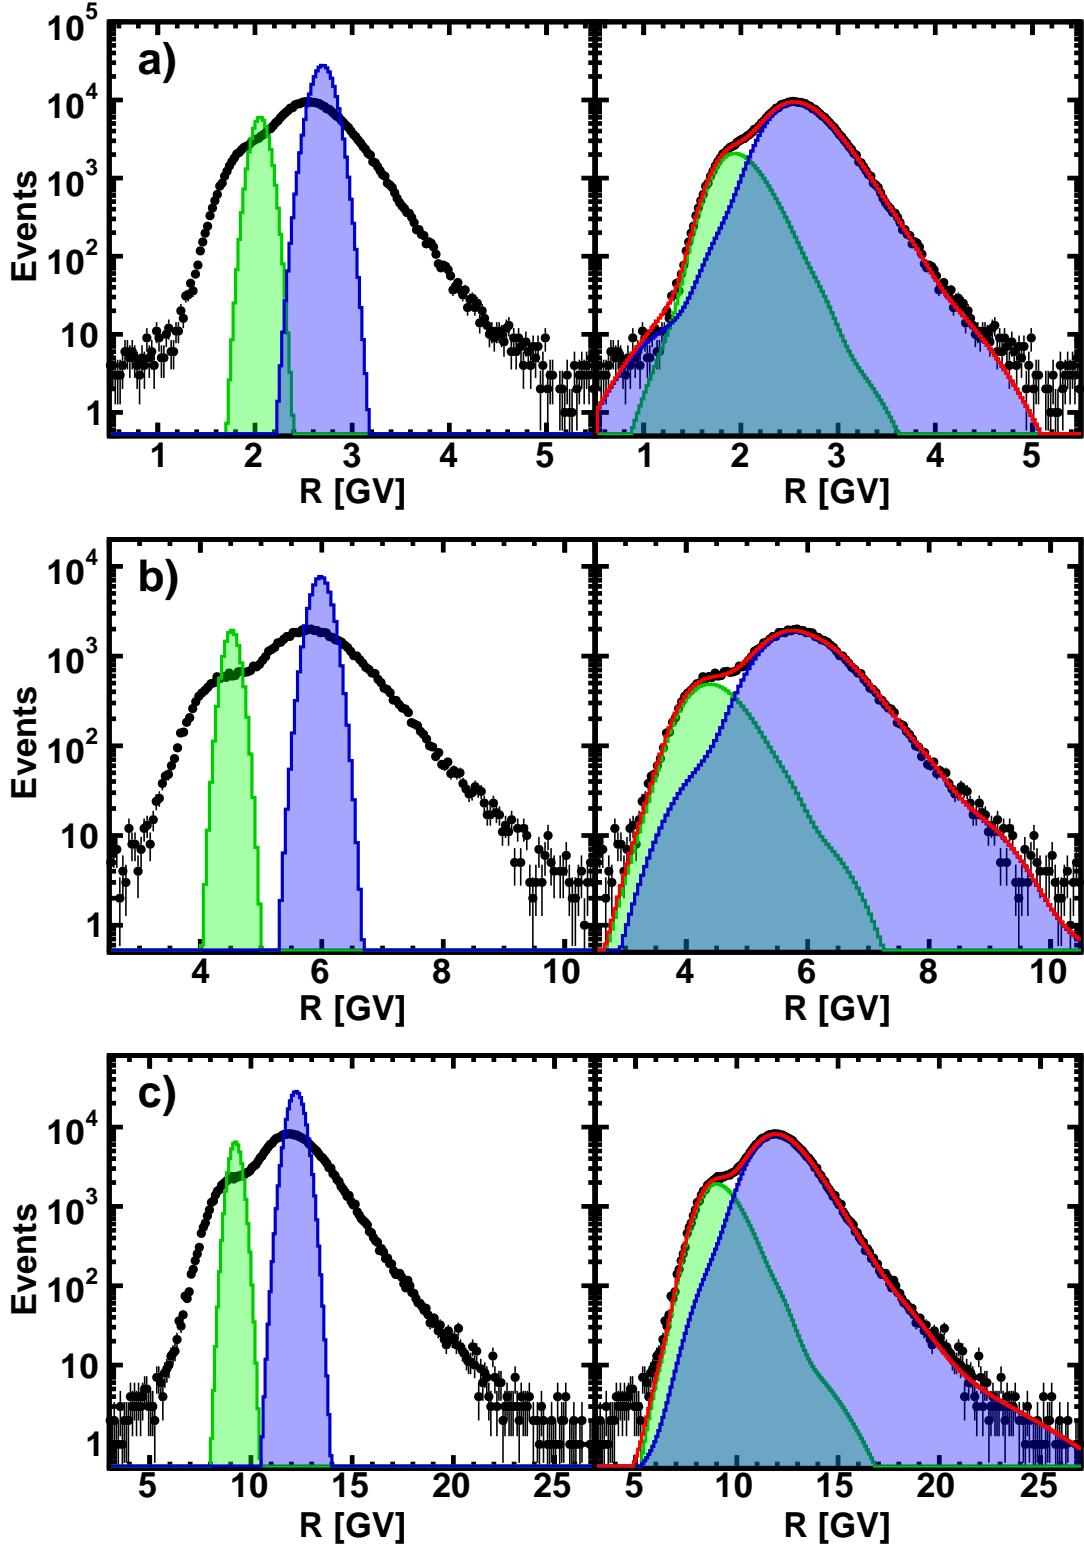

FIG. S2. The rigidity distributions for He data (black points) and for ${}^3\text{He}$ (green shaded area) and ${}^4\text{He}$ (blue shaded area) after unfolding (left) and folded (right) for three velocity intervals selected using (a) the TOF $0.8149 < \beta < 0.8160$, (b) the RICH-NaF $0.9532 < \beta < 0.9537$, and (c) the RICH-Agl $0.9863 < \beta < 0.9864$. The fits (red curves) are obtained by adding the folded ${}^3\text{He}$ and ${}^4\text{He}$ distributions with the rigidity resolution function and they yield $\chi^2/\text{d.o.f.}$ of (a) 137/136, (b) 126/124, and (c) 165/152.

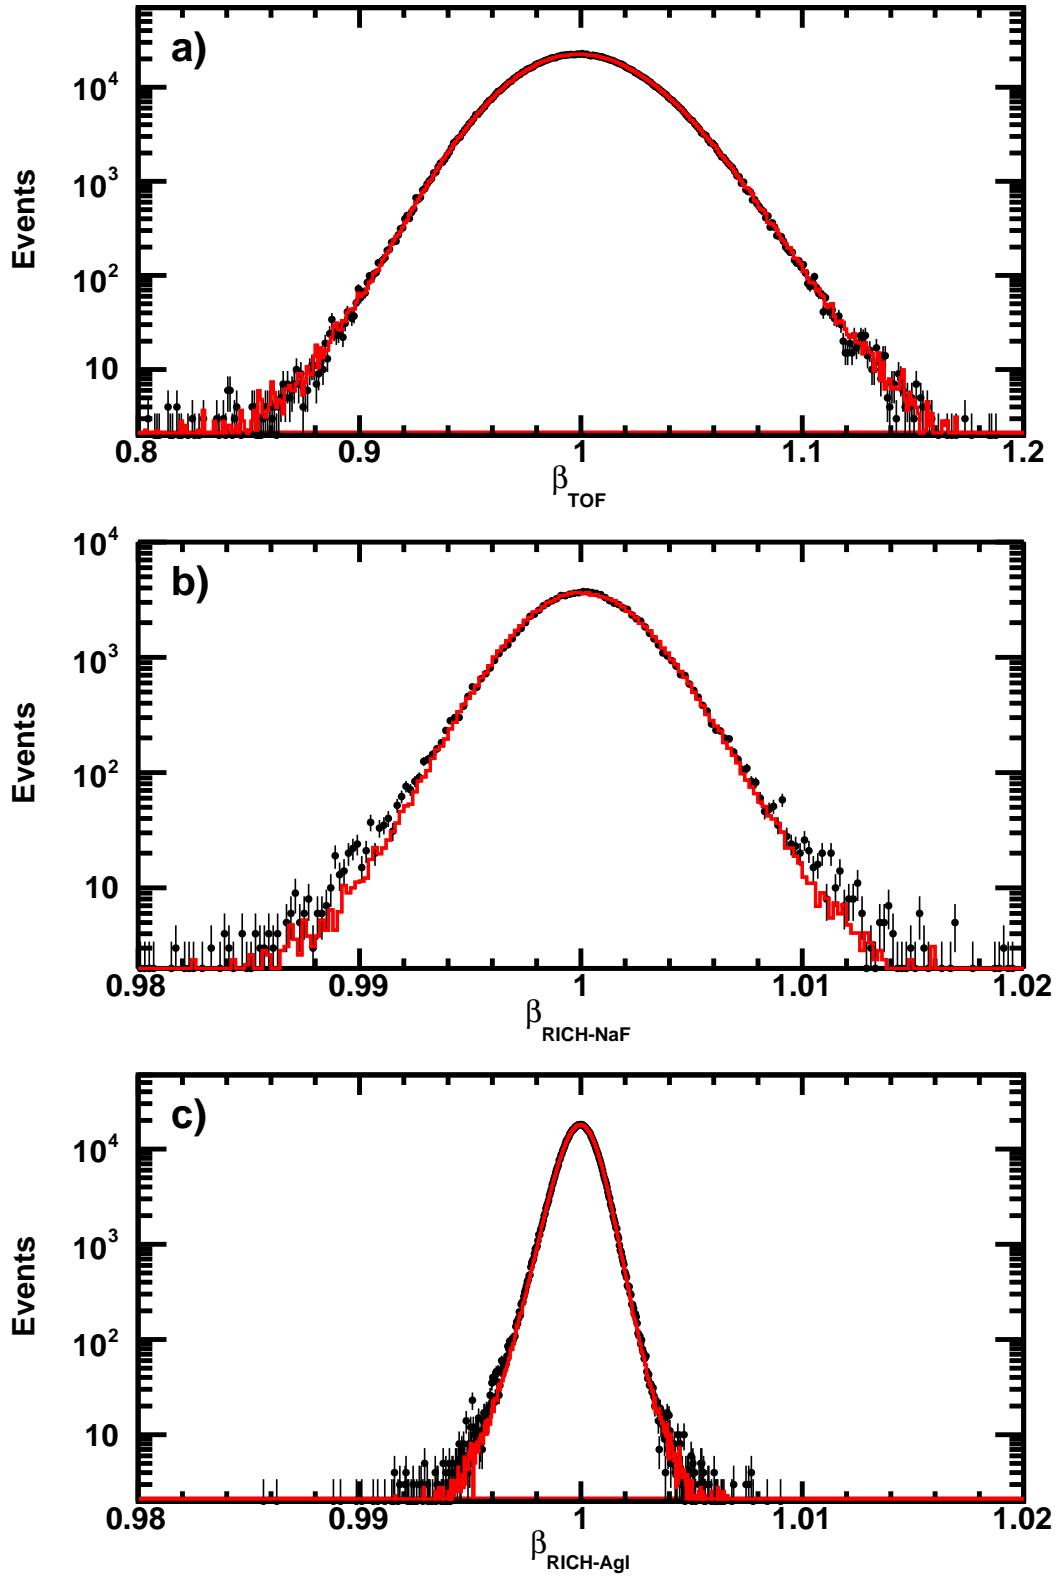

FIG. S3. Helium velocity resolution for $\beta = 1$ selected with $R > 100$ GV for (a) the TOF, (b) the RICH-NaF, and (c) the RICH-AgI, for data (black points) and the MC simulation (red histogram). The velocity resolution is $\Delta(1/\beta) = 0.02$ for the TOF, $\Delta\beta = 25 \times 10^{-4}$ for the RICH-NaF, and $\Delta\beta = 7 \times 10^{-4}$ for RICH-AgI.

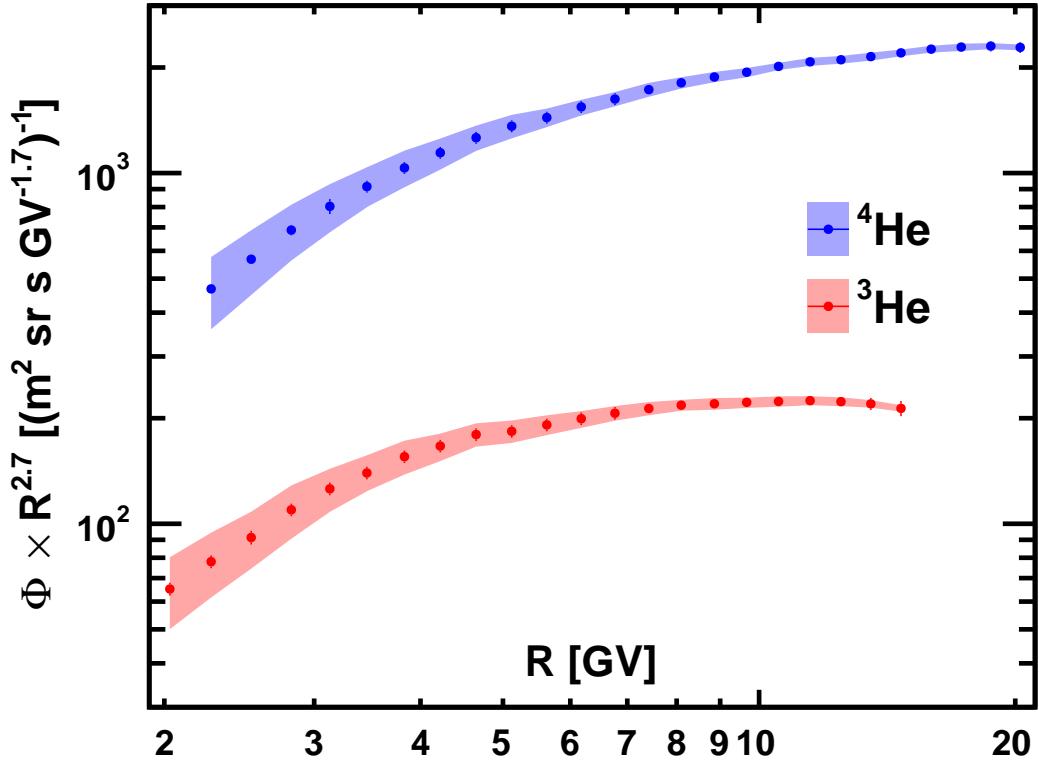

FIG. S4. The AMS time-averaged ^3He (red points) and ^4He (blue points) fluxes multiplied by $R^{2.7}$, as functions of rigidity with total errors. The shaded regions show the range of the time variations.

TABLE SM I. The ${}^3\text{He}$ and ${}^4\text{He}$ fluxes in units of $[\text{m}^2 \cdot \text{sr} \cdot \text{s} \cdot \text{GV}]^{-1}$, and their ratio, as functions of rigidity at the top of AMS, for the time period including Bartels rotation from 2426 to 2429 including errors due to statistical (stat) and systematic (sys.) errors.
